

ApiSpi Appliance — Recommended Network Placement

Governed AI gateway placed in a DMZ / AI-services zone: all LLM and agent traffic is forced through the appliance; direct egress to AI providers is blocked at the perimeter.

Why this placement

DMZ / screened subnet, dual-firewall. The ApiSpi appliance sits in its own AI-services zone between the internal and perimeter firewalls. The internal firewall permits only corporate subnets to reach the appliance on its gateway port; the perimeter firewall permits only the appliance to reach allow-listed AI provider endpoints on TCP 443 — and denies AI API destinations for everything else. This makes ApiSpi the single enforced choke point for all LLM and agent traffic.

Control-plane integration stays internal. The appliance authenticates users against the identity provider (SSO/RBAC decides who may use which models and agents) and streams full prompt/response audit logs to the SIEM — supporting Essential Eight, ISM and PSPF-aligned governance without exposing internal systems to the internet.

Remote users come back in, not around. VPN/ZTNA users reach ApiSpi the same way office users do, so policy, DLP and logging apply everywhere. If you later add cloud workloads, point them at the same appliance (or a cloud-hosted replica) rather than letting them call providers directly.
